Operating Systems:Memory and File System

DS 5110: Big Data Systems (Spring 2023) Lecture 2c

Yue Cheng

The memory hierarchy

Recap: How fast can a CPU run a program?

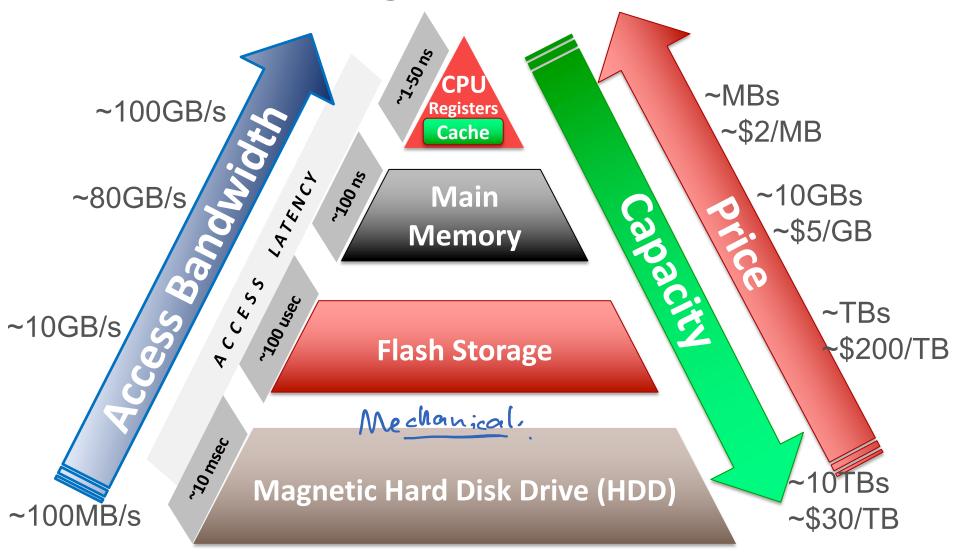

- Most programs do not keep CPU always busy
 - Memory access instructions stall the CPU: i.e., ALU & CU idle during DRAM-register transfer
 - Worse, data may not be in DRAM wait for disk I/O!
 - Actual runtime of a program may be 10-100x higher than what clock rate calculation model suggests

Recap: How fast can a CPU run a program?

- Most programs do not keep CPU always busy
 - Memory access instructions stall the CPU: i.e., ALU & CU idle during DRAM-register transfer
 - Worse, data may not be in DRAM wait for disk I/O!
 - Actual runtime of a program may be 10-100x higher than what clock rate calculation model suggests

Key principle: Optimizing use of CPU caches (and faster storage) is critical for processor performance!

Memory-storage hierarchy

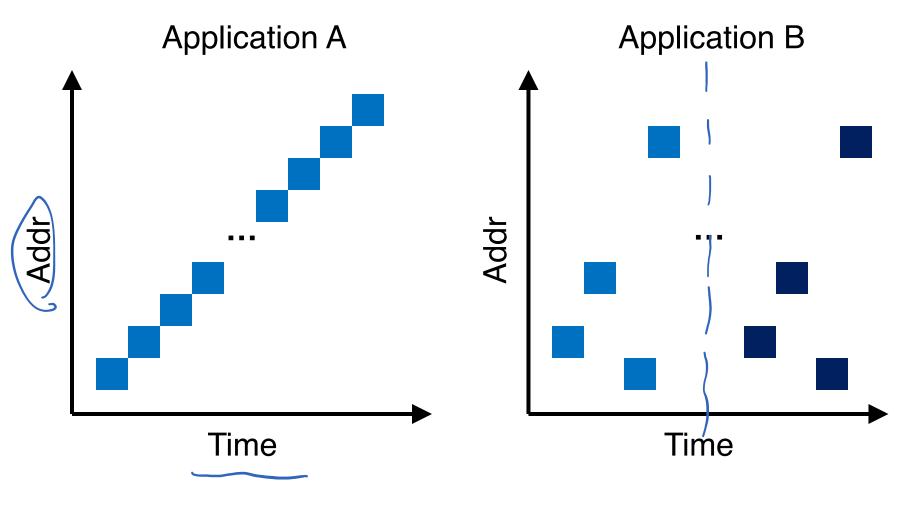

Workload characteristics

Application A

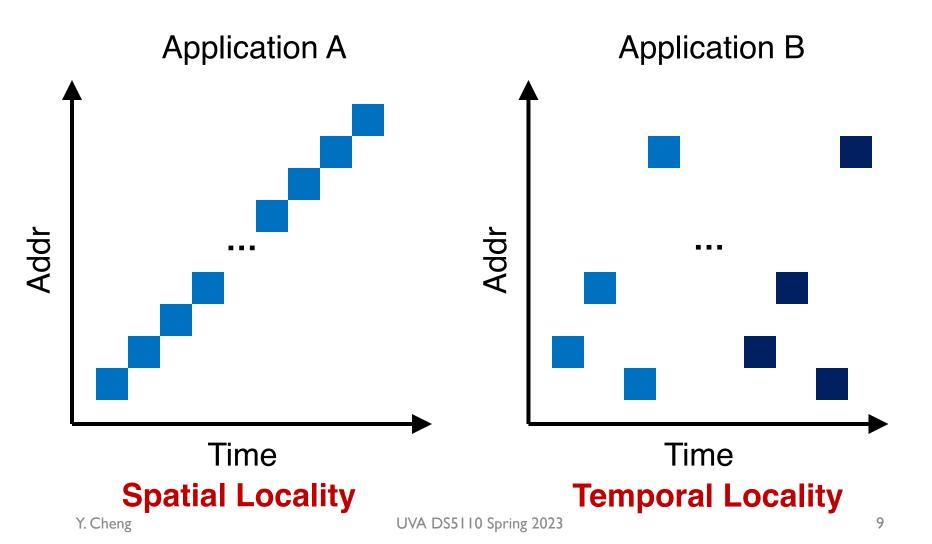

```
sum = 0
for i in range(0,1024):
    sum += a[i]
```

Workload characteristics

Access patterns

Access patterns

Locality of data accesses

- Spatial locality:
 - Future access will be to nearby addresses

- Temporal locality:
 - Future access will be repeated to the same data

Locality of data accesses

- Spatial locality:
 - Future access will be to nearby addresses

- Temporal locality:
 - Future access will be repeated to the same data

 Q: What is the implication of data locality to Data Science applications?

Locality optimization in Data Science

- Consider a tensor (matrix) named data with 128*128 elements
- Each row is of size 128 words and prefetching+caching means full row of accessed data item is brought to CPU cache

Locality optimization in Data Science

- Consider a tensor (matrix) named data with 128*128 elements
- Each row is of size 128 words and **prefetching+caching** means full row of accessed data item is brought to CPU cache

 $128 \times 128 = 16,384$ CPU cache misses

Not too hardware-efficient (not able to exploit prefetching+caching)

DRAM. data 20] [1] ... data 20] [127] - Row O. data [0][1] data [127] [127] -> Row 127 Lata [127][0] ... R3. plata [2][0]

Locality optimization in Data Science

- Consider a tensor (matrix) named data with 128*128 elements
- Each row is of size 128 words and **prefetching+caching** means full row of accessed data item is brought to CPU cache
- Program 1

```
for j in range(0,128):
   for i in range(0,128):
     data[i][j] = 0
```

 $128 \times 128 = 16,384$ CPU cache misses

Not too hardware-efficient (not able to exploit prefetching+caching)

Program 2

```
for i in range(0,128):
   for j in range(0,128):
      data[i][j] = 0
```

dota 20720).
Row D Localed into \$

Only 128 CPU cache misses

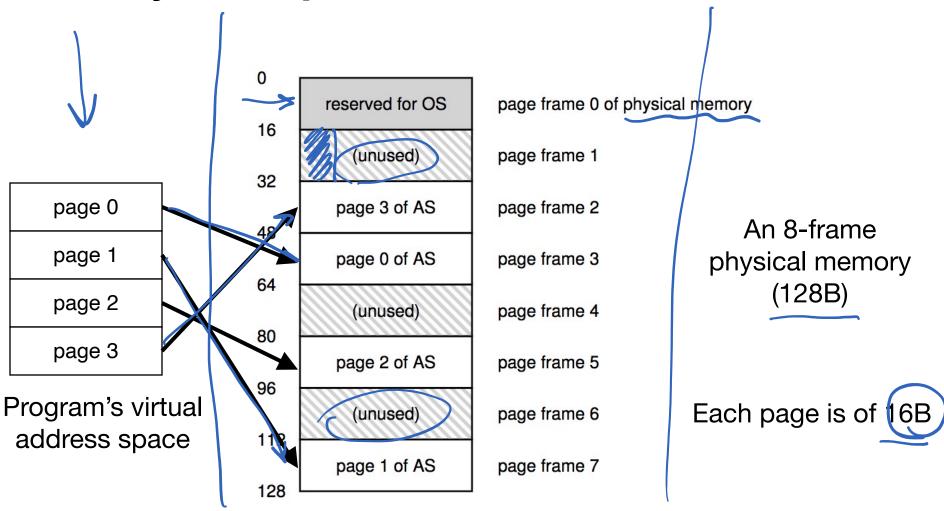

Row data[i] is prefetched to cache so subsequent accesses are hits!

Virtualizing (sharing) memory

OS memory management: Paging

- Paging is a memory management scheme that allows the physical address space of a process to be non-contiguous
- Divide physical memory into fixed-sized blocks called frames
- Divide a program's virtual memory into blocks of same size called pages
- Flexible mapping: Any page can go to any free frame
- Scalability: To run a program of size n pages, need to find n free frames and load program
 - Grow memory segments wherever we please!

A toy example

File system abstraction

What is a **File**?

- File: Array of bytes on a disk
 - Ranges of bytes can be read/written
- File system (FS) is an on-disk data structure that consists of many files

 Files need names so programs can choose the right one

File names

- Three types of names (abstractions)
- inode (low-level names)
- path (human readable)
- file descriptor (runtime state)

Inodes

• Each file has exactly one inode number

Inodes are unique (at a given time) within a FS

Numbers may be recycled after deletes

Inodes

• Each file has exactly one inode number

- Inodes are unique (at a given time) within a FS
- Numbers may be recycled after deletes

- Show inodes via stat
 - \$ stat <file or dir>

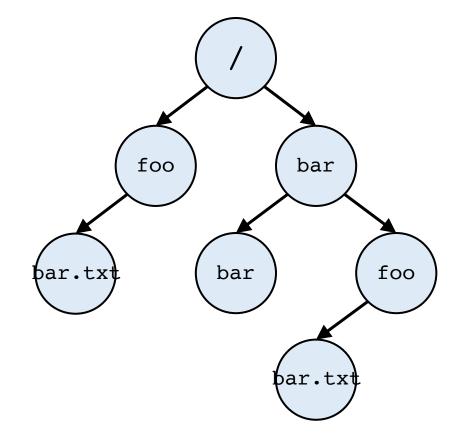

stat example

```
PROMPT>: stat test.dat
File: 'test.dat' Size: 5
                              Blocks: 8
                                            IO Block: 4096
                                                             regular
file
                          Inode: 119341128
                                            Links: 1
Device: 803h/2051d
Access: (0664/-rw-rw-r--) Uid: (1001/
                                            yue)
                                                  Gid: ( 1001/
                                                                    yue)
Context: unconfined u:object r:user home t:s0

```

Path (multiple directories)

- A directory is a file
 - Associated with an inode

 Contains a list of <userreadable name, low-level name> pairs

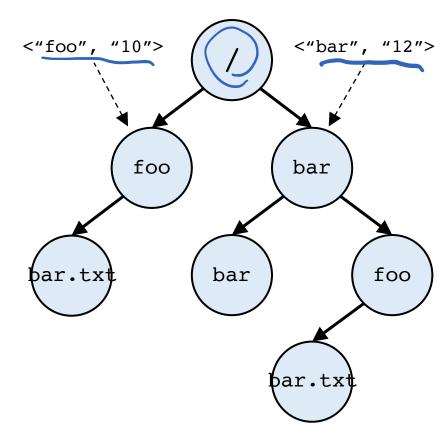

Path (multiple directories)

poot

- A directory is a file
 - Associated with an inode

 Contains a list of <userreadable name, low-level name> pairs

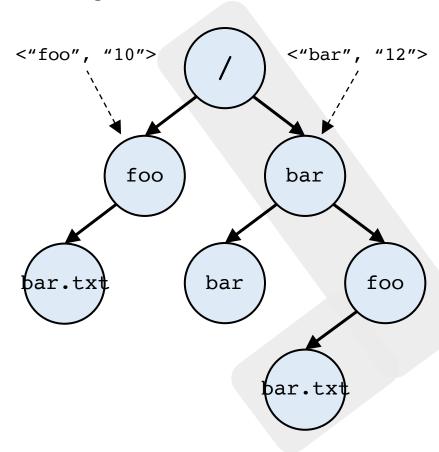

Path (multiple directories)

- A directory is a file
 - Associated with an inode

 Contains a list of <userreadable name, low-level name> pairs

 Directory tree: reads for getting final inode called traversal

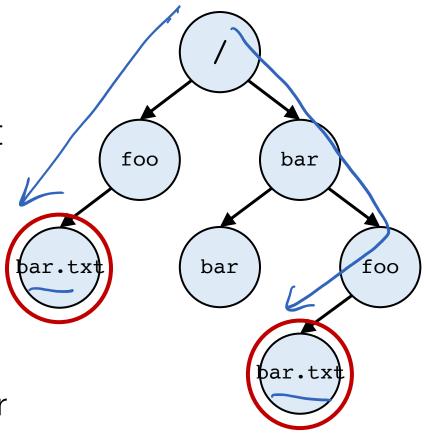

[traverse /bar/foo/bar.txt]

File naming

 Directories and files can have the same name as long as they are in different locations of the file-system tree

- .txt, .c, etc.
 - Naming convention
 - In Linux, no enforcement for extension name

Special directory entries

```
prompt> ls -al
total 216
                           646 Nov 23 16:28

Basic file interactions

Basic file interactions

- Basic file system operations
 - opening/closing
 - reading/writing
- OS-related module
- listdir, mkdir, exists, join

Basic file interactions

- Basic file system operations
 - opening/closing
 - reading/writing
- OS-related module
 - listdir, mkdir, exists, join

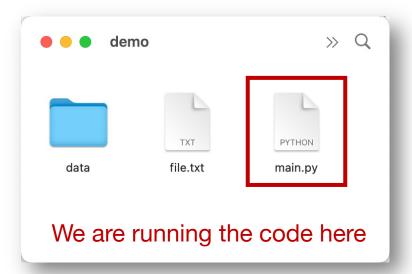

```
f = open(path)
 read data from f
 OR
# write data to f
f.close()
```

Built-in open function open(path) File object File path read data from f OR # write data to f f.close()

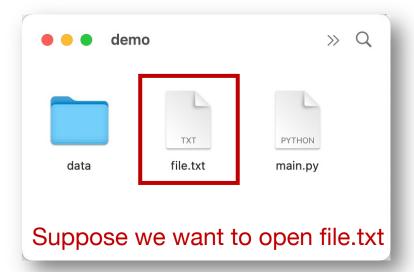

main.py

Built-in open function

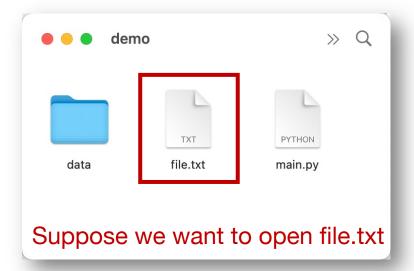

```
open(path)
   File object
               File path
  read data from f
  OR
# write data to f
f.close()
```

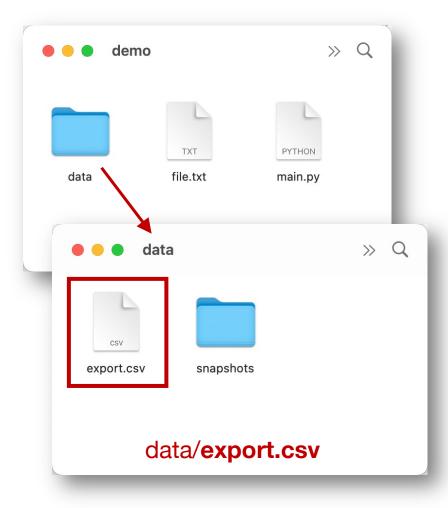

```
Built-in open function
main.py
     open(path)
    File object
                 File path
   read data from f
  OR
  write data to f
f.close()
```

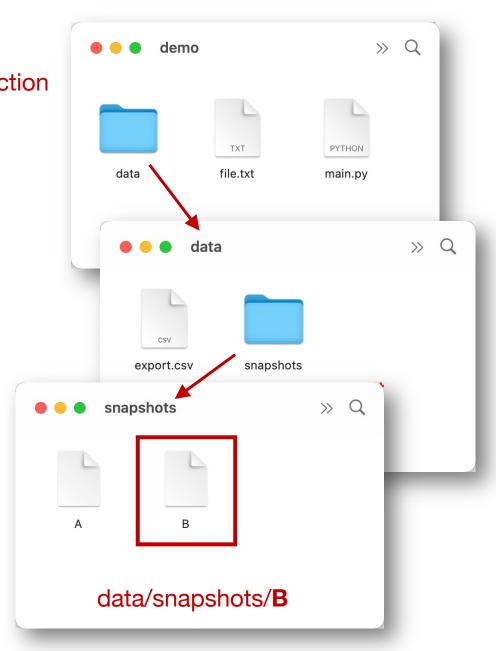

```
Built-in open function
main.py
     open("file.txt")
    File object
                 File path
  read data from f
  OR
  write data to f
f.close()
```

```
Built-in open function
main.py
    open(
  "data/export.csv")
    File object
                 File path
  read data from f
  OR
# write data to f
f.close()
```

```
Built-in open function
main.py
    open(
 "data/snapshots/B")
    File object
                 File path
  read data from f
  OR
  write data to f
f.close()
```

main.py

```
f = open("file.txt")
 read data from f
 OR
# write data to f
f.close()
```

main.py

```
= open("file.txt")
 read data from f
                          Using file
  write data to f
f.close()
```

main.py

```
= open("file.txt")
  read data from f
                           Using file
  write data to f
f.close()
                           Cleanup
```

main.py

```
f = open("file.txt")
f2
```

```
# read data from f
# OR
# write data to f
```

```
f.close()
```

f = open(...) Using file... f.close()

Reasons for closing:

- Avoid data loss
- Limited number of open files

Using file

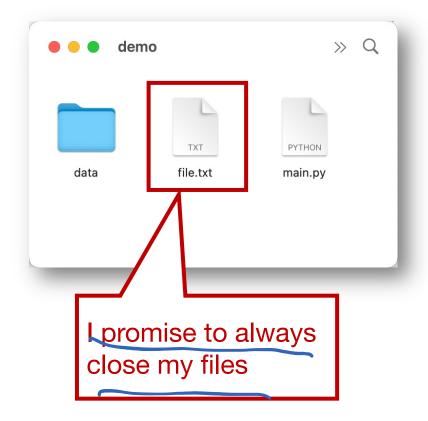

Cleanup

Basic file interactions

- Basic file system operations
 - opening/closing
 - reading/writing
- OS-related module
 - listdir, mkdir, exists, join

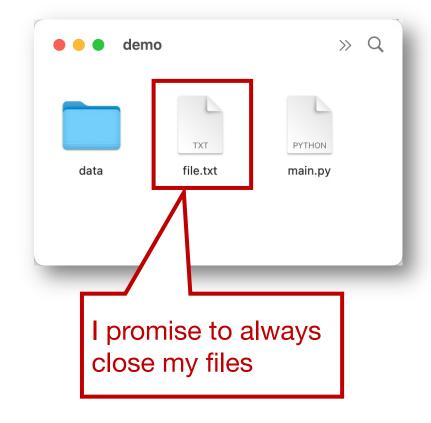

Reading a file

```
f = open("file.txt")
 read data from f
 OR
# write data to f
f.close()
```

Reading a file

```
f = open("file.txt")
data = f.read()
print(data)
```

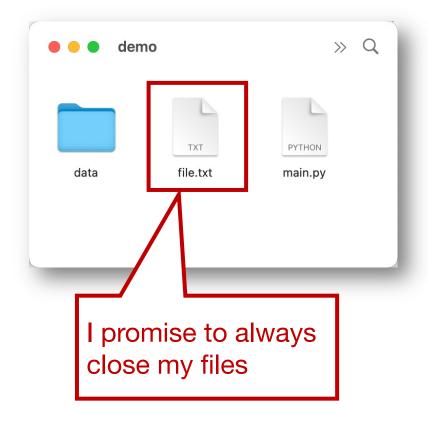

data is: "I promise to always\nclose my files"

f.close()

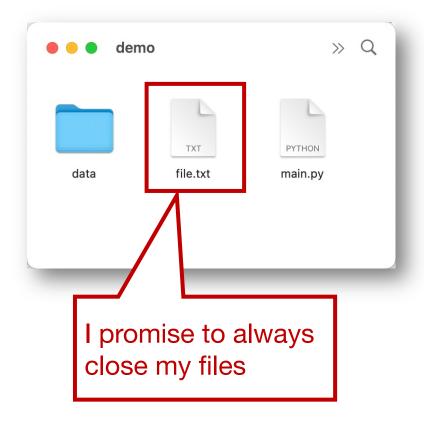

read() method

- Fetch entire content
- Return as a string

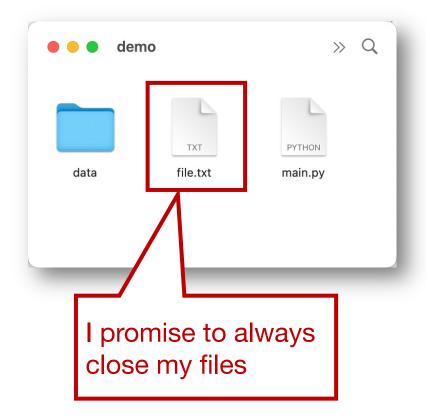

```
f = open("file.txt")
 read data from f
 OR
# write data to f
f.close()
```

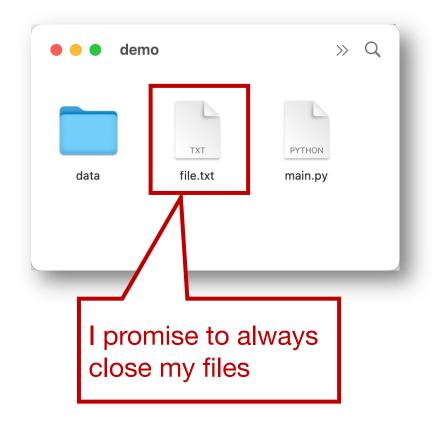

```
= open("file.txt",
           "w" mode indicates
           to write to this file
  read data from f
 OR
# write data to f
f.close()
```

```
= open("file.txt",
     "w"
           "w" mode indicates
          to write to this file
f.write("hello")
f.write(" world\n")
f.write("!!!\n")
f.close()
```

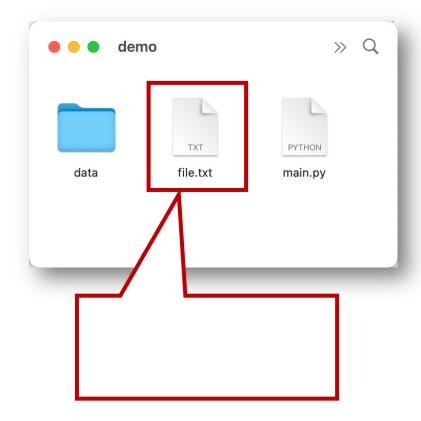

```
open("file.txt",
     "W"
           "w" mode indicates
          to write to this file
f.write("hello")
f.write(" world\n")
f.write("!!!\n")
f.close()
```

Let's run it!

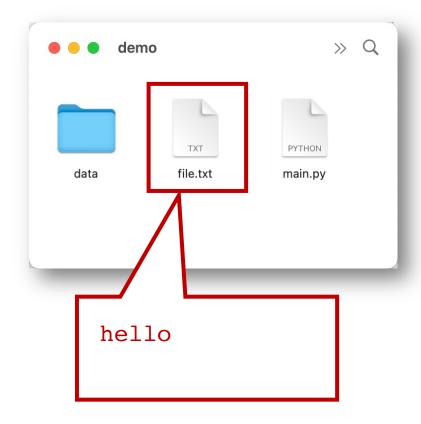

```
open("file.txt",
           "w" mode indicates
          to write to this file
f.write("hello")
f.write(" world\n")
f.write("!!!\n")
f.close()
```

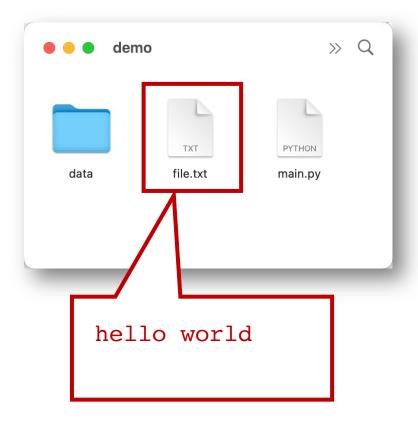

Open with "w" is dangerous. It immediately wipes out your file

(Or create a new one if there isn't already a file.txt)

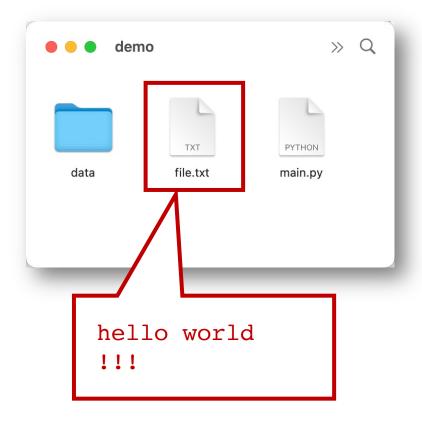

```
= open("file.txt",
     "W"
           "w" mode indicates
          to write to this file
f.write("hello")
f.write(" world\n")
f.write("!!!\n")
f.close()
```

```
= open("file.txt",
     "w"
           "w" mode indicates
          to write to this file
f.write("hello")
f.write(" world\n")
f.write("!!!\n")
f.close()
```

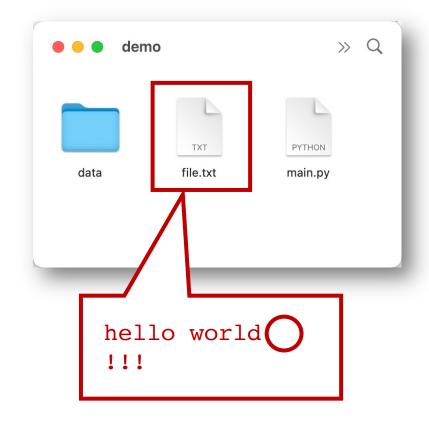

```
= open("file.txt",
     "w"
           "w" mode indicates
          to write to this file
f.write("hello")
f.write(" world\n")
f.write("!!!\n")
f.close()
```

```
open("file.txt",
           "w" mode indicates
          to write to this file
f.write("hello")
f.write(" world(n)"
f.write("!!!\n")
f.close()
```

Be careful with newlines (write doesn't add them like print does)

Basic file interactions

- Basic file system operations
 - opening/closing
 - reading/writing
- OS-related module
 - listdir, mkdir, exists, join

- Many functions in os and os.path for working w/ files
 - os.listdir

Why not use a database?

- 1. It's often an overkill and too heavyweight
- 2. For many situations, writing ad-hoc Python code on a simple CSV/JSON file is easier to use

Next step...

Assignment 1 is out today!

Next week: GFS, MapReduce
